

# Building a Smarter AI-Powered Spam Classifier

## Introduction

We are all very well experienced with receiving spam emails in our mail. We can see separate Spam mail box also. Do you ever wonder how those mails are categorized into spam without notifying us. If that feature not available and if we get those mails as normal mail in our inb ox there is a possibility to click and get trapped. So by using our model we will classify whether a mail received is Spam or not using Machine Learning, from this historical data of mails.

## Load the Required Modules.

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns

# modelling lib
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import LabelEncoder

# Algorithms
from sklearn.tree import DecisionTreeClassifier
from sklearn.neighbors import KNeighborsClassifier
from sklearn.linear_model import LogisticRegression

#Metrics
from sklearn.metrics import accuracy_score
from sklearn.metrics import confusion_matrix
from sklearn.metrics import r2_score
```

## Load the Dataset

```
df = pd.read_csv('/kaggle/input/sms-spam-collection-dataset/spam.csv', encoding='latin-1')  
df.head()
```

## Exploratory Data Analysis

```
df.info()
```

From above we can see unnamed 2, unnamed 3, unnamed 4 are NA. so we can drop them.

```
df.describe()
```

```
# we can drop unnamed 2, unnamed 3, unnamed 4
```

```
df.drop(columns= ["Unnamed: 2","Unnamed: 3","Unnamed: 4"], axis=1, inplace=True)
```

```
df.head()
```

```
df['v2'].value_counts()
```

We can see there are repeated duplicate values. we can remove duplicates.

```
# duplicates
```

```
df[df.duplicated]
```

```
#Removing duplicates
```

```
df = df.drop_duplicates()
```

```
df.head()
```

## Analyze after basic clean of data

```
df.info()
```

```
# description
```

```
df.describe()
```

```
# unique values
```

```
df.nunique()
```

```
# balanced or imbalanced dataset
```

```
df['v1'].value_counts()
```

```
# null values
```

```
df.isnull().sum()
```

## Data Visualization

### Univariate analysis

```
# we have only v1 as categorical so we can use countplot for frequency  
sns.countplot(data= df, x='v1')
```

As we can see from above data set we can see spam has very less spam emails.

### Label Encoding

```
# converting v1 into numerical from categorical  
le = LabelEncoder()  
df['v1']= le.fit_transform(df['v1'])  
df.head()
```

## ML Model Training

```
# X and y features  
X= df['v2']  
y=df['v1']  
X_train,X_test, y_train,y_test = train_test_split(X,y,test_size=0.3, random_state=20)  
X_train.shape,X_test.shape,y_train.shape,y_test.shape
```

## Converting Text into Numerical using TF-IDF vectorizer

```
from sklearn.feature_extraction.text import TfidfVectorizer  
extract = TfidfVectorizer(min_df=1, stop_words='english',lowercase=True)  
# train and test into numerical  
X_train_feat = extract.fit_transform(X_train)  
X_test_feat = extract.transform(X_test)  
# Convert the target values into 0 and 1  
y_train = y_train.astype(int)  
y_test = y_test.astype(int)  
print(X_train_feat)
```

## Training with Logistic Regression

```
lr = LogisticRegression()

lr.fit(X_train_feat,y_train)

y_pred= lr.predict(X_test_feat)

print("Logistic Regression Accuracy score", accuracy_score(y_test,y_pred)*100)

print(confusion_matrix(y_pred,y_test))

print("R-Squared value : ", r2_score(y_test,y_pred))
```

Accuracy score of 95%

## Training with Decision tree Classification

```
dc = DecisionTreeClassifier(random_state=0)

dc.fit(X_train_feat,y_train)

y_pred= lr.predict(X_test_feat)

print("Decision tree Classification Accuracy score", accuracy_score(y_test,y_pred)*100)

print(confusion_matrix(y_pred,y_test))

print("R-Squared value : ", r2_score(y_test,y_pred))
```

## Email Spam Classifier With Machine Learning

### Import Library

```
# Import necessary libraries

import pandas as pd
import numpy as np
from sklearn.model_selection import train_test_split
from sklearn.feature_extraction.text import TfidfVectorizer
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import accuracy_score, confusion_matrix, roc_curve, roc_auc_score
import nltk
from nltk.corpus import stopwords
from collections import Counter

# Libraries for visualisation

import matplotlib.pyplot as plt
import seaborn as sns
```

## Load The Dataset And Explore

```
# Read the CSV file containing email data into a DataFrame

df = pd.read_csv("/kaggle/input/sms-spam-collection-dataset/spam.csv",encoding='latin-1')
df
```

plt.ylabel('Frequency')
plt.title('Top 10 Most Common Words in Ham Emails')
plt.xticks(rotation=45)
plt.show()
```

## Conclusion

We can observe that both the ML algorithms have given accuracy rate of 95%. That is a good accuracy rate for spam email detection. Email spam classification has received a tremendous attention by majority of the people as it helps to identify the unwanted information and threats. Therefore, most of the researchers pay attention in finding the best classifier for detecting spam emails. From the obtained results, fisher filtering and runs filtering feature selection algorithms performs better classification for many classifiers. The Rnd tree classification algorithm applied on relevant features after fisher filtering has produced more than 99% accuracy in spam detection. This Rnd tree classifier is also tested with test dataset which gives accurate results than other classifiers for this spam dataset.
